Geometric constraint solving: several domains, several contexts

- ▶ Education: Statement \rightarrow program of construction;
- ▶ Technical drawing: sketch \rightarrow precise drawing;
- ▶ Architecture, photogrammetry (projections \rightarrow 3D-objects);
- ▶ molecule problem, robotic (distance geometry) ...

We focus here on education.

Program of construction

What a student should do

- ▶ Reasoning gives intermediate objects.
- ▶ Necessary conditions give locii.
- ▶ Discussions give the non-degeneracy conditions.
- ▶ Discussions give the number of solutions (and all the constructions).

→ a notion of literal statement is needed

→ a notion of program of construction is needed

→ Progé mimics a student way of constructing figures

For some reasons, we dispatch the geometric knowledge into the different concepts of our based knowledge system.

- ▶ some knowledge is attached to sorts, functional symbol and predicative symbols
- ▶ high level knowledge is expressed through “production” rules

this allows to consider a geometric universe as a parameter of the system while keeping efficient mechanisms (for instance, unification modulo).

Geometric sorts

```
dmax(droite,2).
autom(droite,D,
      [dir :: Di nomme dird(D)], [dpdir(nul, Di)]).
princip(droite,[dro,dpdir]).
rep_par(droite,d(_,_,_)).
dessinable(droite).
dessine(_, d(A,B,C)) :-
    point_bas(A,B,C,Xb,Yb),
    point_haut(A,B,C,Xh,Yh),
    tbw_draw_line(0,Xb,Yb,Xh,Yh,1,0).
saisie(droite, Nom, d(A,B,C)) :- ...
```

Functional symbols

```
profil(intercc, cercle x droite >> point).  
rmult(intercd).  
decomp(intercd,[cercle/incid, droite/incid]).  
intercd(D1,D2) equiv interdc(D2,D1).  
deg_titre(incid, 1).  
  
'maj:' M eg mil(A,B) ==> [M est_sur dro(A,B)] :- !.
```

Predicative symbols

```
pprofil('=p=', point x point).  
pprofil(ortho, droite x droite).  
pprofil(est_sur, point x lieu).
```

```
ptitre(est_sur, incid).
```

```
constructif(est_sur, incident, 1).  
D ortho DD pequiv DD ortho D.
```

Rules (1)

```
2 # si [ did(A,D) '=1=' H]
    et
    [connu D, connu H, pas_connu A]
alors
  [ A est_sur dpd(D,H) : 1].
```

Rules (1)

```
3 # si [ did(A, dro(B,C)) '=l=' L]
    et
    [connu A, connu B, connu L,
      différents [B, prj(A, dro(B,C))],
      pas_connu C]
alors
  [
    H nomme prj(A, dro(B,C)),
    H est_sur cdiam(A,B),
    H est_sur ccr(A,L) : 1
  ].
```

Rules (1)

```
7 # si [did(A,D1) '=1=' did(A,D2)]
   et
     [différents [D1,D2], connu D1,
      connu D2, pas_connu A]
alors
  soit [dird(D1) diff dird(D2)]
    et [ A est_sur bis(D1,D2) : 1]
  ou
    soit [dird(D1) eg dird(D2), D1 diff D2]
      et [A est_sur dmd(D1,D2) : 1]
  ou
    soit [D1 eg D2] et [].
```

```
is_fe(fe(_,_,_,_,_,_)).  
fe_nom(fe(Nom,_,_,_,_,_),Nom).  
fe_type(fe(_ Typ,_,_,_,_), Typ).  
deg_lib(fe(_,_ D,_,_,_), D).  
fe_def(fe(_,_,_ Def,_,_), Def).  
fe_reprs(fe(_,_,_,_ Lr,_), Lr).  
fe_parts(fe(_,_,_,_,_ Lp), Lp).
```

Formal figure

```
ajoute_rep(Terme, FeE, FeS) :-  
    not(decomposable(Terme)), !,  
    ajoute_repr(Terme, FeE, FeS).  
ajoute_rep(Terme, FeE, FeS) :-  
    decomposable(Terme, Ltit),  
    ajoute_parts(Ltit, FeE, FeS).
```

Formal figure

```
ajoute_repr(Terme,  
            fe(Nom, Ty, D, Def, Reprs, Parts),  
            Fe) :-  
    appartient_rep(Terme, Reprs), !,  
    Fe = fe(Nom, Ty, D, Def, Reprs, Parts)  
;  
    D == 0, !,  
    Fe = fe(Nom, Ty, D, Def, [Terme|Reprs], Parts)  
;  
    construit(Terme), !,  
    Fe = fe(Nom, Ty, 0, Terme, [Terme|Reprs], Parts)  
;  
    Fe = fe(Nom, Ty, D, Def, [Terme|Reprs], Parts)
```

Each object has a name in Progé.

For instance, if you consider $\text{prj}(A, \text{dro}(B,C))$, Progé creates a line with name `droite05` containing points `A` and `B`, and a point, say `point12`, with the equality $\text{point12} = \text{prj}(A, \text{droite06})$

If there is a point, say `p1` which is already equal to $\text{point12} = \text{prj}(A, \text{droite06})$ no new point is created, instead, point `p1` is updated.

As a consequence, internally, the terms have at most depth 1.

- ▶ Usually, objects with different names are considered different.
- ▶ But, when you consider degeneracy, you must consider equalities between points, lines, etc.
- ▶ In Progé, when objects are declared as equal, they are fused ... which is a heavy operation.

When 2 objects becomes equal, we have two names (at least for the same object).

We use a tree to deal with this equivalence relation (*designing the same object*) through a predicate named `alias/2`

The root of the tree is the privileged name for the object.

The unification process must take *all* the information contained in the figure into account.

For instance, if you have to unify $\text{mil}(a,b)$ with $\text{interdd}(l1, d)$, the system looks for names to $\text{mil}(a,b)$ and to $\text{interdd}(l1, d)$ into the figure.

Now, if you have to unify m with $\text{mil}(X, \text{interdd}(d1,Y))$ the system will try all the objects which are equal to $\text{mil}(X1,X2)$ and then try to unify $X2$ with $\text{interdd}(d1,Y)$.

The atomization operation, the alias predicate and the argument permutations are widely used in the process.

Graph of reasoning

In order to prevent infinite loops, Progé keeps a trace of the applied rules together with the facts used to apply them.

Each discovered comes from an atomization process! For instance, $\text{dist}(a,b) = 11$ becomes $11 = 11$ and the *figure* contains the information $\text{dist}(a,b) = 11$

The history is a graph, where the nodes are the atomized facts and the edges the rules used to derived them. Plus some control informations.

Graph of reasoning

```
sommet_num(sommet(Num, _, _, _), Num).  
sommet_prop(sommet(_, Prop, _, _), Prop).  
sommet_nba(sommet(_, _, Nba, _), Nba).  
sommet_nbp(sommet(_, _, _, Nbp), Nbp).
```

```
deriv_num(deriv(Num, _, _), Num).  
deriv_clause(deriv(_, Clause, _), Clause).  
deriv_n_regle(deriv(_, _, Nregle), Nregle).
```

Rule application

There are several strategies to choose a pair (rule, list of facts).

When a rule is chosen, the system try to instantiate it by searching in the graph reasoning *and* the figure.

For instance, in the parallelogram exercise, the statement contains the fact $\text{dist}(a,x) + \text{dist}(b,y) = l$ which is atomized in $l = l$ with the informations

$\text{long01} = \text{dist}(a,x)$ and $\text{long02} = \text{dist}(b, y)$ and $l = \text{long01} + \text{long02}$ stored in the formal figure.

Reasoning (continued)

Considering the rule:

```

300 # si [dist(A,M) + dist(B,N) '=1=' L]
    et
        [connu dro(A, M) ]
alors
[
  X nomme interdc(dro(A,M), ccr(A,L)),
  A est_sur ccr(X,L),
  dist(X,M) '=1=' dist(B,N),
  tinhibe(300)
].

```

the system has to search for a fact using a distance equality and then to unify: $\text{dist}(A,M) + \text{dist}(B,N) '=1=' L$ with $1 '=1=' 1$

Reasoning (continued)

Unification is done mostly by using the figure (and possibly permutation rules)

Then the system tests if $\text{connu_dro}(A, M)$

if all succeeds, the rule is *possibly* applied. In fact, in order to have a fair use of the deduced facts, we implement a kind of breadth-first search by using nba and nbp numbers.

Link(s) with the figure

When a rule succeeds, new facts and new objects.

If an object o is constructed (that is, its degree of freedom becomes 0), a definition $o=t$ is inserted in the construction plane,

But ... things are more complicated when the function symbol is interpreted by a multifunction (giving a foreach ... in ... do structure).

Link(s) with the figure (continued)

Things are even more complicated when there exists preconditions for applying the function related to the functional symbol:

- ▶ the system tries to proof that the precondition(s) holds, if it it is ok, then ... it is ok;
- ▶ if it fails, it tries to proof the negation of the precondition, if it succeeds, the negation of the precondition is added to the facts (usually more specific knowledge is associated);
- ▶ if both proofs fail, then a if ... then ... else structure is added in the program and a context is pushed on a stack of contexts.

Links with the application of disjunctive rules

This is more or less the same mechanism when the system applies a disjunctive rule:

- ▶ if there are additional conditions, the system try to prove them ...if it fails, it puts a particular structure (foreach case in a list of cases). Note that the additional conditions are not forcefully testable as they are interpreted during the interpretation of the program construction.
- ▶ if there are no additional conditions, the system put a if... then ... else structure in the program.
